## Analysis

Khan Academy's sign-up page provides users with three options before registration: Student, Family member, or Teacher. This is a useful feature because it allows the registration process to be tailored to the user's needs and makes the purpose of the account clear from the beginning. The page is easy to understand and supportive, as users are given clear options rather than being presented with a registration form without any context. The clean layout and additional "Did you know?" information also make the page more interesting and engaging.

The page does, however, differ from the conventional way users may expect a registration process to work. Instead of immediately presenting the registration form, users must first select their role. While this adds another step and may slightly affect efficiency. The role selection provides useful personalisation and makes the registration process more relevant to different types of users. This demonstrates an important consideration for Jakob's Law: although users benefit from familiar registration processes, introducing a small variation can still be effective when it provides a clear benefit to the user.

Another issue is the large amount of unused white space surrounding the content. Although the simple layout keeps the page uncluttered, the available space could potentially be used more effectively. A more compact design, such as presenting the registration process in a pop-up, could allow users to focus on the registration options while making better use of the screen.

Overall, Khan Academy's sign-up page follows familiar registration principles while introducing a useful role-selection feature. This supports Jakob's Law by maintaining an understandable and recognisable registration process, while the role selection demonstrates that familiar conventions can be adapted when doing so provides additional value to the user.

## Analysis

Khan Academy's login page follows a conventional login structure, with the email and password fields presented clearly and familiar options such as "Forgot password?" and a link to create an account. This familiarity supports Jakob's Law, as users are likely to recognise how the page works without needing to learn a new interaction pattern. The page is also supportive because it provides password requirements, a password visibility option, and multiple authentication methods.

The multiple authentication options make the login process flexible and potentially more efficient, as users can choose the method that is most convenient for them. The initially disabled login button may also be slightly unclear to some users because it does not immediately communicate why it cannot be selected.

Overall, the login page strongly follows Jakob's Law by using familiar login conventions and interactions. Rather than introducing an unfamiliar authentication process, Khan Academy uses patterns that users are already likely to understand. The page therefore demonstrates that a design can remain conventional while still providing additional features that improve flexibility and usability.
